ALUMINA AND ALUMINUM PLANT NEAR JUNG-YANG, CHINA

An alumina and aluminum plant near Jungyang, China, was observed on photography of The plant is located six nautical miles west-northwest of Jung-yang at 34-49N 113-15E. It is served by a spur of the rail line between Cheng-hsien and Lo-yang (Figure 1). The plant occupies a total ground area of approximately 300 acres (Figures 2 and 3).

25X1

At the time of photography the plant was not in operation and some sections of the plant were not completed. Smoke, fumes, or dust, normally associated with the alumina-aluminum industry, were not visible. The absence of construction equipment and activity within the plant area indicates that construction has apparently stopped.

Photographic interpretation reveals that the plant when finished will be completely integrated, i.e., the installation will comprise facilities for the production of alumina and the production and fabrication of aluminum (Figure 2 and Table 1). However, essential components of certain facilities are under construction or missing. In the alumina section (Section B) the caustic recovery building (Item 16) is not completed and about half the number of precipitators (Items 17 and 18) are not in place. Vertical supports (adjacent to Items 6 and 22) have been constructed for two additional rotary kilns in this section. The small quantity of red mud in the basins (Item 1) indicates that the alumina section has facilities adequate at least for a trial run.

In the aluminum reduction section (Section C) two potrooms (Item 26), each measuring 1,180 by 80 feet, have been constructed; the

size and position of the rectifier building (Item 28) indicates that construction of two more potrooms is planned. The transformer yard, usually located near the rectifier building, is not installed. The absence of an associated electric power plant suggests that electric power will be provided by the local power net.

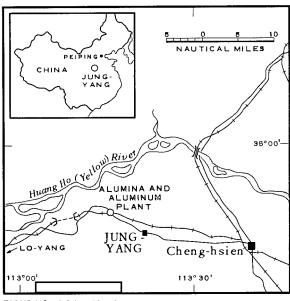

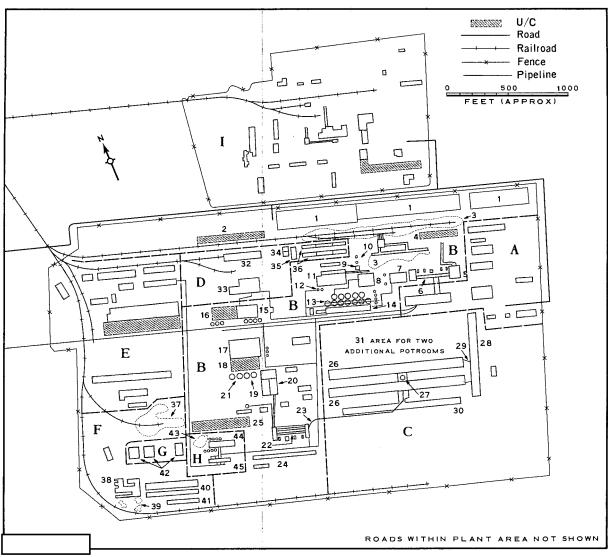

FIGURE 1. LOCATION OF ALUMINA AND ALUMINUM PLANT NEAR JUNG-YANG, CHINA.

One production building is under construction in the rolling mill and fabrication section (Section E). Bauxite, other raw materials, and fuel are stored in the open in the plant area.

The presence of a lime-soda-sinter section (Section I) is an indication that the bauxite to be processed at this plant will have a high silica content. The presence of red mud basins, numerous precipitation tanks, and rotary kilns indicate that the Bayer process will be used at the plant for the production of alumina.
